東盲蝽属 Pilophorus Hahn, 1826 是叶盲蝽亚科 Phylinae 東盲蝽族 Pilophorini 中最大的属,目前已知 100 余种,广泛分布于古北区、东洋区及新北区,非洲区记录 1 种,新热带区和澳洲区无记录。邹环光 (1983, 1985, 1987, 1989) 在東盲蝽属中描述了 5 个新种,齐宝瑛、能乃扎布(1996)在记述内蒙古地区捕食性盲蝽时记述了 2 种,郑乐怡(1995)年在中国盲蝽名录中记述了東盲蝽属 16 种。目前我国共记载 18 种,包括本文描述的 2 个新种。

束盲蝽属的主要鉴别特征 体狭长,束腰形,部分种类强烈束腰成明显蚁形;体色多为黄褐或栗色,少数种类黑色;体表常被两种毛:一种为深色、半直立或平伏状刚毛状毛,另一种为银白色或金黄色鳞片状毛,呈点斑状、带状排列于小盾片基部两侧及顶角处、半鞘翅基部 1/3 及 2/3 处、楔片基部、中、后胸侧板后缘及腹部;爪狭长,无爪垫,副爪间突呈窄片状肉垫,端部相互靠近。

雄性生殖囊中等大小,约占整个腹面的 1/4~1/5,阳茎端狭长,骨化强烈,呈"L"形或"C"形,端部具纤细、狭长的骨针,周围包裹宽大的膜叶,膜叶基部具较粗的短刺,阳茎端近中部常具 1 长片状突起,形状多样;左阳基侧突舟形,右阳基侧突叶片状;阳茎鞘骨化强烈,端部具尖锐或圆钝。

根据文献记载及作者在野外的观察,本属寄主 广泛,在木本及草本植物上均有发现,但多以乔木、 灌木上为主,热带雨林等潮湿、阴暗环境尚无记载。 模式标本均保存在南开大学昆虫学研究所。

TWO NEW SPECIES OF THE GENUS PILOPHORUS HAHN FROM CHINA (HEMIPTERA, MIRIDAE, PHYLINAE)

ZHANG Xu, LIU Guo-Qing * Institute of Entomology, Nankai University, Tianjin 300071, China

Abstract In this paper, two species belonging to genus Pilophorus Hahn from China are described as new to science. They are: P. elongatus sp. nov. and P. fortinigritus sp. nov. The type specimens are deposited in the Institute of Entomology, Nankai University, Tianjin. The measurements are in millimeters.

Pilophorus elongatus sp. nov. (Figs. 1-2, 5-9)

Body elongate, moderately ant-mimetic.

Head relatively small, rather declined; vertex flat, posterior margin weakly concave, with short carina; labium slender, reaching to anterior margin of mesocoxae, segment reddish brown, remainder yellow-brown with apex deep brown; antennal segment

dirty yellow, proximal two-thirds of segment brown with remainder deep brown, proximal two-thirds of segment and anterior apex of segment yellowwhite with remainder of the two segments deep brown.

Pronotum black, anterior margin slightly convex,

lateral margin weakly constricted mesially, posterior margin almost straight. mesoscutum exposed black. Scutellum black, weakly protuberant mesially, laterally with two distinctly dense patches of scalelike setae. Hemelytra yellow-brown, rather elongate, weakly constricted laterally; covered with sparse, golden, appressed setae; scalelike setae arranged into two bands on corium. Cuneus brown, without scalelike setae.

Abdomen brown to brownish black, basally rather constricted.

Male genitalia. Vesica L-shaped, with a slender, lanceolate projection on shaft, laterally mesially with a tiny denticle (Fig. 5); hypophysis of left paramere elongate, blunt apically (Figs. 6-7), right paramere leaflike (Fig. 8); phallotheca, beaklike apically (Fig. 9).

Holotype , Ningan County (44 21 N , 129 28 E) , Heilongjiang Province , 12 Aug. 2003 , collected by YING Tian. Paratypes: 1 ,5 ,same data as holotype.

^{*} Corresponding author.

Etymology. Named for the obviously elongate appearance.

Similar to P. aureus Zou in body shape and coloration, separated from P. aureus Zou by the scalelike setae on cuneus, and the form of vesica. Scalelike setae on cuneus of P. aureus Zou present and the projection of vesica with a thumblike, relatively elongate process.

Pilophorus fortinigritus sp. nov. (Figs. 3-4, 10-14)

Body black, with two transverse bands of scalelike setae on hemelytra (Figs. 3-4).

Head transverse in dorsal view, weakly projecting anteriorly; frons and vertex black, posterior margin of vertex forming a straight carina; labium brown-black with apex yellow-brown, almost reaching to abdominal segment; antennal segment brown-black dorsally and yellow-brown ventrally, proximal two-thirds of segment deep brown with remainder black, segment and yellow-white with distal apex of segment weakly darkened.

Pronotum black, transversely broad, weakly swollen, covered with black, recumbent setae; anterior margin weakly convex, lateral margin straight, anterolateral angle respectively with a black, erect spinelike setae, posterior margin weakly concave

mesially. mesoscutum exposed black, weakly declining. scutellum black, flat; with straight bands of scalelike setae on lateral margin; hemelytra generally black, with two transverse bands of scalelike setae; cuneus brown-black, weakly declining, broadly triangular.

Abdomen black, broad, strongly shining.

Male genitalia. Vesica L-shaped, with a spinelike, lanceolate, nearly vertical projection on shaft (Fig. 10); left paramere stout, hypophysis elongate, sensory lobe blunt, weakly curved (Figs. 11-12); right paramere leaflike (Fig. 13); phallotheca small, apex blunt (Fig. 14).

Holotype , Taishun County (27 33 N , 119 42 E) , Zhejiang Province , 31 July 2005 , collected by BU Wen-Jun. Paratypes : 2 ,2 ,same data as holotype.

Etymology. The name referring to the distinctly robust appearance and black coloration of body.

Similar to P. latus Zou in body appearance, separated from P. latus Zou by scalelike setae on hemelytra and scutellum arranged into distinctly regular, dense, and shining bands, whereas that of P. latus Zou forming two rather broad, incompact bands on hemelytra and scattered uniformly on scutellum.

Key words Hemiptera, Miridae, Phylinae, Pilophorus, new species.
